

A short document on Gas Pressure from a “flat Earthers” perspective.
2024 Version 0.1 (edit.3)

Modus Ponens logical syllogism

If (the air we breathe is gas at pressure) “**P**”, *then* (the air we breathe must be contained) “**Q**”,
“**P**” (the air we breathe is gas at pressure), *Therefore* (the air we breathe must be contained) “**Q**”.

Gasses expand rapidly in all directions; they originate from Earth’s surface level, or come up from underground, dispersing in to the available volume in all directions in 360° vertically, diagonally & horizontally in our 3D world.

Flora intake and expel gasses, same with fauna, same with humans, and all those reside on Earth, and mostly confined to its surface. And the gasses originating from underground either get stuck there for us to dig to, or released through cracks or fissures etc..

If the first gas molecule came out the ground, maybe rose up through water & broke its surface, it would then just carry on moving in the same direction (up), and keep going until it collided with something to change its direction.

If the gas molecule had no container to collide with, then it would just leave Earth and never come back, and by not remaining, never contribute to the generating of gas-pressure we call air, which we breathe.

If the gas molecule left by rising up, then the next one too, and the next and the following, then gas pressure, or air, would never have been achieved & thus we humans, or flora, or fauna, would never have been able to exist.

However; gas pressure does exist, and we do breathe it as air at roughly 14.7 PSI (pounds per square inch) from sea-level.

- How would you or I transport some gas?
- Would you maybe require a container to do so?
- Would it have to be a closed container, “air-tight”?
- How about transporting a lack of gas or severely low pressure, a simple vacuum, would you require a container to do so?

Gas pressure’s defined as the collisions of the gas molecules with the walls of the container, they have elastic collisions and expand rapidly to fill the available volume.

Considering a container and a given volume’s required to have gas-pressure, for the molecules to “bounce around in”, how is it that mere mortals are claiming to have gone to & through a “vacuum of outer-space”!? Or even sent machines to traverse a so called “vacuum of outer-space” professed to be just above our heads!?

This would mean a violation of the 2nd law of thermodynamics, in which Entropy’s not occurring, having the gas not fill the available volume of “the vacuum of outer-space”.

“Outer space” is an interesting way to say; region that’s not inside the container. Yet no container is mentioned when sending man and machine through its paradoxical non-existence.

In other words; “the vacuum of outer-space” is faked, and isn’t traversed, nor could it exist as told.

If you loved “space movies” then I feel for you, I was once in your shoes too.
However, I have great news; notice the difference between “space” and “outer-space”.

Space is very real, it’s the distance between my location and your location, it’s usually described in 3D as we live in a 3D world, and gas fills all that space.

But to get to an imagined “outer-space”, you’d certainly have to encounter a container first. [I like to imagine *astro-nots* stopping at a great wall like in the Truman show, entering the secret door in to a decompression chamber, you know, to not kill all the rest of us on Earth as they leave.. then exiting out of another door..] a little tongue and cheek there.

First you require a container, then you can achieve gas, then as it’s contained, you’ll achieve gas-pressure. But people like to point to lower gas-pressure readings at higher elevations, compared to the 14.7 PSI at surface level. They’ll assert this with just; “gas-pressure gradients”.

Well, to have gas-pressure gradients, you first need gas pressure, and to have gas pressure, you’ll need containment. However that overlooks the idiotic notion that lower-pressure gas would be containing higher-pressure gas from escaping Earth to fill the presupposed available volume so called “vacuum of outer space”. How’s less pressure containing higher pressure!? Self-defeating isn’t it.

Other people like to incorrectly & fallaciously beg the question of “the force of gravity contains the gas”, when gravity’s not been described as a force for 109 years, and rather been described as a conceptual pseudo 4space effect, and not a cause of something, therefore not containing anything, and still overlooking the fact that gas expands in all directions and is not being generated in the sky, for us to be blessed with falling gas to breathe.

- I’ve even had to explain to someone that plasma is not gas, whilst they were so sure that they’d found gas pressure without a container, they presented contained gas and an electromagnetic field to contain plasma, which is not gas. Which doesn’t really trump someone else presenting 3 containers for a demonstration of gas pressure without a container. Amazing.

- I find this heliocentric monkey business the masses all believe in without question, insulting to human intelligence. How’s one breathing air in an ever expanding natural law violating fairy-tale!?

The sun’s presupposed to be a concentrated ball of gas, in an ever expanding vacuum!?

You might need to read that one again; “concentrated ball of gas in a vacuum”.

Yet “vacuum of outer-space men” need suits to go violating Entropic law. How considerate.

You can’t violate Entropic law (2nd law of thermodynamics). And the Roman Catholic “Big Bang” violates the 1st law of thermodynamics (which ironically proves a creator; not a random event of nature crating itself).

Gas pressure of 14.7 PSI at sea level and decreasing as we rise up vertically.

This is a pressure reading, with respect to a horizontal plane of reference for multiple positions and thus different readings in the vertical. Another subtle flat Earth nod. But also, some reasons for higher pressure at lower levels would be due to more things for the gas molecules to be colliding with, when compared to the emptiness of the sky, or up a snow-topped mountain like Everest, and considering the regenerating or recycling of gases by flora and fauna, and other such events like evaporation, all of which is occurring at surface level, which are things that aren’t occurring in the sky directly above your head or above the clouds.

When we think of weight, we're referring to how heavy something is, in the medium of air. If something of substance weighs a lot, we say it's heavy, and we need more force to lift or move it. The reason we have to use more force, is to overcome the density differential that is naturally there, where the density of the medium of air is lesser to that of the heavy weight, the heavy weight would be much easier to lift or move if it were in a medium that is denser than air, like for example the ocean, or liquid mercury which is extremely dense & can float a blacksmith's anvil at its surface, you can move the anvil with just 1 finger. With this in mind, the weight of the anvil is now essentially nullified with respect to the medium of liquid mercury, it no longer is seeking down, it's risen up and is floating at & protruding the surface making it feel "weightless" to our touch. The anvil didn't change, only the medium did, *and how much does the anvil weigh now*; you can move it with 1 finger and if you had extremely dense scales and placed them inside the mercury on the floor of the container; the anvil floating above has no weight to register on the scales as it's not in contact with them at all, it's simply displacing the mercury at the surface.

Short YouTube video of an anvil floating in liquid mercury: [click here](#)

Also see my "Relative Density" pdf (*links below*) for more on that.

If we weigh something in air on some scales, and then place the scales and the object in a vacuum chamber and extract gas, the object will begin to "weigh more" as the gas we breathe has pressure and that generates a "buoyant effect" on the object; by removing or minimizing that air pressure in the vacuum, you're minimizing the gas molecule collisions with the object, there's then less molecules hitting the object that are going up or diagonally in an upward direction, therefore less lift effect experienced by the object & thus weighing more than usual (in air). Similar to helium balloons rising up in air, but in a vacuum, they eventually fall once the medium has been greatly reduced. These counter the notion of "gravity" pulling things down.

Likewise when people say they can weigh gas by weighing an "empty" container, then inserting gas and weighing it again, it will weigh more now compared to prior. Considering the container is never truly empty, it's not a perfect vacuum inside, the container would implode with the air pressure from the outside if it were, the "empty" container is at equal pressure to that of the air you're breathing. A filled container will have much higher pressures than what we breathe as air, therefore increasing in pressure induces more weight, as there's now more matter. And we know that more pressure is due to more collisions inside the container. And thus we know that the "more weight" or the "weight of the gas pressure added" is not truly the weight of the quantity of gas added, as the weight being registered is only of the gas molecules hitting the bottom of the container to be registered on the scales at any point in time, however there are walls in a 360° and a ceiling or top to that container that are also experiencing gas molecule collisions which are not contributing to the down weight being registered on the scales.

A short video clip I took from NathanOakley1980 on YouTube: [click here](#)

I'll close with this again;

Modus Ponens logical syllogism

If (the air we breathe is gas at pressure) "**P**", **then** (the air we breathe must be contained) "**Q**",
"P" (the air we breathe is gas at pressure), **Therefore** (the air we breathe must be contained) "**Q**".

My message, intentions and disclaimers:

- I'm documenting my findings on various topics within the "flat Earth" subject, with a series of downloadable pdf-files to then share in digital and/or physical formats, maybe even eventually compile a small book out of it all.
- With updates, later editions of these documents should be more detailed & comprehensive for the average reader.
- I number each document every time I update it, I mark them with an alias name, document title, version and year so that the reader has the ability to identify & download the latest one.

A message to my peers:

- I wish to inspire others to do the same, but I feel I must lead with example, no one needs to hear *"please write everything you just said down & make charts and diagrams so I can better understand your position"*, but I found myself drawing on images and pinning copies of my responses in my notes to save time detailing points I kept finding my "debate opponents" not comprehending or re-asking ad-nauseam.
- Whilst making a simple diagram, I thought, *why isn't "everyone" trying to concisely detail flat Earth sub-topics and points of contention in document format?* I appreciate that I am not privy to all documents ever created by all "flat Earthers" ever, and I'm not claiming to be the pioneer of making a pdf-document either, but for my intended purposes, "opponent's requirements" and my wishes to inform people, I don't see a reason why "we" shouldn't be creating these kinds of documents and making them available for free to the average person, share them with your peers, print them out and share them with family or friends. No family member of mine is interested in multi-hour long podcasts (regardless of the topic).
- I'd like to suggest documenting the topics you're most interested and/or proficient in, share them with your peers, update & refine to make them as concise but informative as possible & then share them with your peers again for further constructive criticism, to ultimately collectively organise a mass of documents detailing every possible sub-topic of "flat Earth". This way we "pave the paths" for people that are new to the topic of "flat Earth", rather than expecting them to sift through hundreds of thousands of hours of content to maybe only receive broken messages, half understandings and/or fragments of arguments.

One should always do their own research to validate the content for themselves, this way bad documents get exposed &/or corrected. (peer-review)

My personal Links:

- The Hub (Discord Server), you can find & download my PDFs in here [#downloads](#) (free to download & free to use) (includes documents on: "Relative Density", "Scientific Method", "Gas pressure prerequisite container" ...)
- You can contact me through Discord, via [The Hub](#) server for any corrections or additions etc..
- Github archive coming soon! (this is so ANYONE can find these documents, with zero requirement of a user account, as you can only see INSIDE of my Discord server, if you have a Discord account... which is NOT ideal)

Thank you for reading

@TM_theviking
